Frontend Engineering Intern - Take-Home Assignment

Welcome! Thank you for your interest in joining the engineering team. To evaluate your frontend development skills, we have designed a practical take-home assignment. This project reflects the type of product architecture and problem-solving you will encounter daily.

Project Overview

Your task is to build a responsive **Weather Dashboard** that allows users to search for cities and view current and forecasted weather data. We highly recommend utilizing **Next.js** for this application.

Core Implementation Task

Develop the main weather application interface featuring the following capabilities:

- **Search Functionality:** Implement a search field allowing users to input a city name and trigger a data fetch.
- **Current Weather Display:** Showcase the temperature, humidity, wind speed, and a descriptive weather icon for the queried location.
- **Forecast Display:** Present a 5-day weather forecast in a clean, easily readable layout.
- **Data Integration:** Connect to a free public API (such as OpenWeatherMap or WeatherAPI) to populate the application with real data.

Notes:

- Ensure proper error handling (e.g., displaying a user-friendly UI state if an invalid city is entered or the API fails).
- Implement loading states while fetching data to prevent layout shift and provide a smooth user experience.
- You may use your preferred CSS strategy (Tailwind, CSS Modules, Styled Components), but the final design must be responsive across mobile and desktop viewports.

Evaluation Criteria

- **Component Architecture:** Clean, reusable, and modular component structure.
- **State Management:** Efficient handling of application state, API lifecycle, and user inputs.
- **UI/UX Design:** A responsive, intuitive interface. Attention to typography, spacing, and overall polish matters.
- **Code Quality:** Readable, cleanly formatted code without unnecessary complexity.

Bonus / Nice-to-Have Features

If you want to push the application further, consider implementing:

- **Geolocation:** Automatically fetch and display the weather for the user's current location upon initial load.
- **Search History:** Save and display the most recent searched cities using local storage for quick access.
- **Unit Toggle:** Allow users to seamlessly switch the global display between Celsius and Fahrenheit.

Submission Guidelines

- Host your source code on a public GitHub repository.
- Deploy the application to a hosting platform (e.g., Vercel, Netlify) and include the live URL at the top of your repository's README.
- Provide clear instructions in your README on how to install dependencies and run the application locally.
